## FOREWORD

A joint feasibility study for producing a combined climatological/oceanographic atlas of the water areas of the world was undertaken by the Naval Weather Service Command and the Naval Oceanographic Office in 1969. The results of this feasibility study revealed a twofold increase in surface marine observations over the Indian Ocean basin since Volume III of the U.S. NAVY MARINE CLIMATIC ATLAS OF THE WORLD was published. The additional data plus recommendations for revised content and format, provided by various Naval Weather Service fleet units and field activities, warranted the updating of the entire series of marine climatic charts of the world.

The Naval Weather Service Detachment, Asheville, was tasked to produce a technical model of the atlas providing a sample of each type of page presentation proposed with supporting documentation. The atlas mock-up was approved by Headquarters, Naval Weather Service Command in 1971 as the model for Volume I (1974) as well as for this atlas and future volumes of this series. Volume III has followed production of Volume I because of intense scientific interest in the Indian Ocean Basin. Volume II, The North Pacific, will follow this volume in the publication sequence.

## ACKNOWLEDGMENT

The revision of the U.S. NAVY MARINE CLIMATIC ATLAS OF THE WORLD series is managed by the Naval Weather Service Detachment, Asheville by direction of the Commander, Naval Weather Service Command. This volume was prepared at the National Climatic Center.

Specific acknowledgement is made to the following members of the National Climatic Center; Project Leaders Messrs. J. M. Meserve, R. G. Quayle and D. C. Fulbright; Messrs. J. D. Elms, A.W.Y. Chen and H. F. Diaz for their assistance in the editorial evaluation and analyses of the data; Messrs. R. H. Courtney, R. G. Baldwin, D. Swann, E. Gilreath, Mrs. D. T. Hawkins and Miss E. Cook for drafting.

The oceanographic part was based upon data provided by the U.S. Naval Oceanographic Office, whose contribution is acknowledged with thanks.

# PART I - METEOROLOGY

## INTRODUCTION

The eight volume series of the U.S. Navy Marine Climatic Atlas of the World has had wide acceptance as an authoritative reference for large scale operational planning and applied research. This volume, based on nearly 120 years of data (1854-early 1973), is an update of Volume III (U.S. Navy Marine Climatic Atlas of the World, 1957) and is designed to fulfill the same requirements. This volume is not, however, a one for one revision. Some of the data presentations have been changed and wave statistics have been added. There are no upper air charts presented since in recent years several comprehensive volumes of upper air data have been published separately: (*Upper Wind Statistics Charts of the Northern Hemisphere*, Volumes I and II, NAVAER 50-1C-535, 1959; *Components of the 1000 MB Winds of the Northern Hemisphere*, NAVAIR 50-1C-51, 1966; *Selected Level Heights, Temperatures and Dew Points for the Northern Hemisphere, including Monthly Mean Wind Speed and Direction*, NAVAIR 50-1C-52, 1970; *Selected Meridional Cross Sections of Heights, Temperatures and Dew Points of the Northern Hemisphere*, NAVAIR 50-1C-59, 1971; *Climate of the Upper Air: Southern Hemisphere, Volume I, Temperatures, Dew Points, and Heights at Selected Pressure Levels*, NAVAIR 50-1C-55, 1969; *Volume II, Zonal Geostrophic Winds*, NAVAIR 50-1C-56, 1971; *Volume III, Vector Mean Geostrophic Winds*, NAVAIR 50-1C-57, 1971; *Volume IV, Selected Meridional Cross Sections of Temperature, Dew Points, and Height*, NAVAIR 50-1C-58, 1971).

The descriptive explanations which follow give details concerning the quality control and processing of the observations, the development of the charts and graphs and a few possible applications of the various charts. Also discussed are limitations imposed by the quality of the data and the methods adapted to help overcome them.

This Atlas is the result of a concerted and extensive effort by many people (aided by automatic data processing equipment) to present a detailed and useful ocean climatology.

## THE GENERAL PLAN OF THE CHARTS

The "point statistics" of land climatology are made possible by the maintenance of weather records at fixed locations for long periods. Such statistics are not generally available for Ocean Basins. Where the number of observations is sufficient, it is possible to select areas small enough to permit an approximation to the "point statistics" of land stations. For this Atlas 45 such representative areas are used. The locations are outlined on the base chart and numbered. The graphs and tables computed for these areas have been placed on the facing page for ready reference to the base chart.

## THE OBSERVATIONS AND THEIR PROCESSING

Variations in definitions, codes and units of measurements used by maritime nations for recording and punching marine observations have resulted in 18 different forms (or "decks") of punched cards available for use at the National Climatic Center. These data have been converted to a common format and placed on magnetic tape. For a more detailed explanation of the conversion procedures, the reader is referred to the *Tape Data Family-11 (TDF-11) Reference Manual* (National Climatic Center, 1968). This tape deck was the primary data source for this volume. Funding for the development of TDF-11 was provided primarily by the Naval Weather Service Command with supplemental support from the National Oceanic and Atmospheric Administration (NOAA), formerly ESSA, and the Department of Defense.

The data were subjected to complex quality control procedures before processing. First, duplicate observations (which entered the data base from different sources) were eliminated. The remaining observations were then checked for internal consistency. Elements which failed to meet the internal consistency checks were either adjusted or eliminated. The data were subjected to an extreme value check in which the highest and lowest values of appropriate elements were listed and checked. These quality controlled data have been retained in a separate tape file designated as the U.S. Navy Marine Atlas Work Tapes.

Regardless of the amount of quality control to which marine observations are subjected there are many inherent problems which can be corrected in only a general way. Among these are: the difficulty in taking observations of meteorological elements from an unstable platform, different levels of observer experience, recording errors, variations in observing and coding practices, punching errors, the scarcity of observations over vast areas, and the effect of weather

elements themselves on measurements. Ships may avoid bad weather when possible (Quayle, 1974), thus decreasing the amount of bad-weather data; or they may slow down in foul weather, thus taking more observations and increasing the data sample.

Complete observations (including all elements) from transient ships are steadily becoming more common. Ships' weather logs of past decades, incomplete by today's standards, show wind direction and speed to be the elements almost invariably recorded. From a survey of the data available for this atlas, the percentage of observations containing other basic weather elements is as follows:

Element	Percent
Air Temperature	98
Sea Temperature	92
Total Cloud Amount	78
Visibility	72
Sea Level Pressure	56
Present Weather	57
Low Cloud Amount	36
Wet Bulb Temperature	36
Waves	26

Because of incompatible observing or coding procedures, many observations of total cloud amount, visibility, present weather, low cloud amount, and wave data have been eliminated from the computations. This significantly reduced the percentages of these elements in the above table.

Some peculiarities of selected elements are listed below:

**PRECIPITATION** — Of all of the elements recorded in historical marine observations, precipitation is one of those most subject to error in interpretation. This derives from a number of causes such as coding practices, observers' preference for certain present weather codes and other biases.

**SEA SURFACE TEMPERATURE** — This element is recorded with a fairly high frequency in marine observations. The various methods of recording, however, tend to decrease the reliability of the individual values. Gradients and relative values are considered to be reliable.

**SEA LEVEL PRESSURE** — This element is one of the least accurate because of instrument, coding and conversion errors. To be capable of registering accurate pressure readings, barometers used on shipboard generally require more frequent calibration than they receive. Despite the inaccuracies of the individual readings, however, the large scale patterns and gradients are relatively accurate.

**AIR TEMPERATURE** — This element is considered to be generally reliable. However, in the tropics, as the result of poor instrument exposure, observed temperatures on transient ships under sunny conditions appear consistently high. This data subset influences primarily the distribution of maximum temperatures (99th percentile) while the minimum

elements themselves on measurements. Ships may avoid bad weather when possible (Quayle, 1974), thus decreasing the amount of bad-weather data; or they may slow down in foul weather, thus taking more observations and increasing the data sample.

Complete observations (including all elements) from transient ships are steadily becoming more common. Ships' weather logs of past decades, incomplete by today's standards, show wind direction and speed to be the elements almost invariably recorded. From a survey of the data available for this atlas, the percentage of observations containing other basic weather elements is as follows:

<i>Element</i>	<i>Percent</i>
Air Temperature	98
Sea Temperature	92
Total Cloud Amount	78
Visibility	72
Sea Level Pressure	56
Present Weather	57
Low Cloud Amount	36
Wet Bulb Temperature	36
Waves	26

Because of incompatible observing or coding procedures, many observations of total cloud amount, visibility, present weather, low cloud amount, and wave data have been eliminated from the computations. This significantly reduced the percentages of these elements in the above table.

Some peculiarities of selected elements are listed below:

**PRECIPITATION** — Of all of the elements recorded in historical marine observations, precipitation is one of those most subject to error in interpretation. This derives from a number of causes such as coding practices, observers' preference for certain present weather codes and other biases.

**SEA SURFACE TEMPERATURE** — This element is recorded with a fairly high frequency in marine observations. The various methods of recording, however, tend to decrease the reliability of the individual values. Gradients and relative values are considered to be reliable.

**SEA LEVEL PRESSURE** — This element is one of the least accurate because of instrument, coding and conversion errors. To be capable of registering accurate pressure readings, barometers used on shipboard generally require more frequent calibration than they receive. Despite the inaccuracies of the individual readings, however, the large scale patterns and gradients are relatively accurate.

**AIR TEMPERATURE** — This element is considered to be generally reliable. However, in the tropics, as the result of poor instrument exposure, observed temperatures on transient ships under sunny conditions appear consistently high. This data subset influences primarily the distribution of maximum temperatures (99th percentile) while the minimum

(1st percentile) and mean temperatures are relatively unaffected.

**VISIBILITY** — It is difficult to measure visibility at sea because of the lack of reference points. Also, some observers report reduced visibilities at night because of darkness. The coarseness of the coding intervals, however, tends to minimize serious biases in the summarized data.

**WAVE DATA** — Suitable quantitative wave records are available only since the late 1940's. This, coupled with an apparent reluctance on the part of many observers to take wave observations, particularly in the early years, leaves waves as the least often recorded element in marine observations. The estimate of wave heights is very subjective and depends upon the experience of the observer and the size of the ship from which the observation is taken. Wave heights reported by most transient ships tend to be low by about 10% when compared to reference measurements. Adjustment for this apparent bias has not been made in this Atlas.

Despite the lower confidence level in the individual values of these elements, through subjective analyses and reference to previous studies, the means, extremes and gradients presented by the isopleths are considered to be quite reliable.

## THE ISOPLETH ANALYSES

The climatic data in this atlas are presented by isopleths (lines connecting points of equal magnitude) supplemented by graphs and tables. The isopleth analyses were completed cooperatively by a team of meteorologists. The basic charts were automatically plotted from one or two degree area summaries for the entire ocean basin. As there were no Ocean Weather Station (OWS) data for the Indian Ocean, a valuable tool which was available to analysts in the North Atlantic was lost. Analysts made considerable use of the observation count which was plotted with all summarized data to aid in data interpretation. For the ocean areas southward of 45°S, data were very sparse, thus not affording detailed analyses. Isopleths in these areas should be considered only as presenting a 'best estimate' of the actual climatology.

## THE GRAPHS AND TABLES

To supplement the isopleth analyses, graphs and tables are presented for each representative area. The graphs and tables, in most instances, represent the objective compilation of available raw data for specified areas without regard to suspected biases or inconsistencies.

Since the final isopleth analyses reflects both objective and subjective considerations, differences may be found when comparing the graphical data for a representative area with the analyses.

# THE INDIVIDUAL SURFACE CHARTS

The legend in each chart is designed to explain data content — tables, graphs and isopleths. Each legend contains detailed instructions on how to read the tables or graphs. The following paragraphs contain additional remarks likely to be of interest to those called upon to interpret the data and provide answers to specific operational questions.

Most of the graphs and tables allow approximation of the empirical probability of occurrence of selected criteria. This is a major factor in assessing the risk involved in operational planning. For certain elements, standard deviations are given on the graphs to provide a measure of relative variability. The standard deviation of these graphs is denoted by 's' and was computed using the expression:

$$s = \left[ \frac{N \sum x_i^2 - (\sum x_i)^2}{N(N-1)} \right]^{1/2}$$

where N denotes the number of observations in the sample and  $x_i$  denotes the value of the random variable X. The use of (N-1) in the denominator gives the best estimate of the population standard deviation.

## SURFACE WINDS

Surface wind is the element most commonly observed and recorded. It was the element considered basic in the selection of representative areas for construction of complete frequency distributions. Wind distribution is presented by a combination of two graphic forms — the bar graph and the contingency table. The bar graph corresponds to the percent scale at the top of the square and gives ready reference to the wind direction frequency. The contingency table gives the percent frequency of each wind speed class within each direction. By adding the totals lines at the bottom of the graph it is possible to approximate the percent frequency of wind speed occurrence for selected criteria. For the example graph in the legend, 71% of all winds were < 17 knots.

Persistence statistics would be of interest in planning operations, but these are not possible without serially complete observations from fixed points.

## AIR TEMPERATURE

The threshold value of  $\geq 20^\circ\text{C}$  for the isopleths of air temperature was selected in response to requests by a number of users who considered that relative degree of warmth to be operationally significant for outside marine activity. The mean temperature for each wind direction and calm is shown by dots in the graph opposite each direction and corresponding to the temperature scale at the bottom. Note the temperature range and scale may vary from area to area and month to month.

## T-H INDEX AND TEMPERATURE EXTREMES

The American Society of Heating and Ventilating, as early as 1923, introduced a term called "effective temperature" which is a measure of comfort based on temperature and humidity. This is the term we call THI (Temperature — Humidity Index). It has been empirically determined that a majority of people will be uncomfortable when the index reaches  $24^\circ\text{C}$ . THI is computed by the following equation, adapted from one described by E. C. Thom, 1957:

$$\text{THI} = 0.4 (T_d + T_{wb}) + 4.7778$$

where:  $T_d$  = Dry Bulb Temperature ( $^\circ\text{C}$ )  
 $T_{wb}$  = Wet Bulb Temperature ( $^\circ\text{C}$ )  
 THI is in degrees Celsius

Isopleths of the 1% and 99% levels of air temperature have been selected to present extreme temperature conditions. The graphs show air temperature versus wind speed. Use may be made of these charts to determine the extent of discomfort likely because of extreme heat or cold. They may also be used to estimate the likelihood of superstructure icing.

Ice accretion is a complicated process that depends upon sea conditions, temperature, wind and the size and behavior of the ship. Superstructure icing can affect all ships but is more dangerous for smaller vessels. Icing potential exists when the air temperature falls below the freezing temperature of sea water (usually about  $-2^\circ\text{C}$ ) with wind speed equal to or greater than 11 knots. The lower the temperature and higher the wind speed, the greater the icing potential. Ice accretion may become quite severe with temperatures  $\leq -9^\circ\text{C}$  and wind  $\geq 34$  knots.

## AIR TEMPERATURE

The threshold value of  $\geq 20^{\circ}\text{C}$  for the isopleths of air temperature was selected in response to requests by a number of users who considered that relative degree of warmth to be operationally significant for outside marine activity. The mean temperature for each wind direction and calm is shown by dots in the graph opposite each direction and corresponding to the temperature scale at the bottom. Note the temperature range and scale may vary from area to area and month to month.

## T-H INDEX AND TEMPERATURE EXTREMES

The American Society of Heating and Ventilating, as early as 1923, introduced a term called "effective temperature" which is a measure of comfort based on temperature and humidity. This is the term we call THI (Temperature - Humidity Index). It has been empirically determined that a majority of people will be uncomfortable when the index reaches  $24^{\circ}\text{C}$ . THI is computed by the following equation, adapted from one described by E. C. Thom, 1957:

$$\text{THI} = 0.4 (T_d + T_{wb}) + 4.7778$$

where:  $T_d$  = Dry Bulb Temperature ( $^{\circ}\text{C}$ )

$T_{wb}$  = Wet Bulb Temperature ( $^{\circ}\text{C}$ )

THI is in degrees Celsius

Isopleths of the 1% and 99% levels of air temperature have been selected to present extreme temperature conditions. The graphs show air temperature versus wind speed. Use may be made of these charts to determine the extent of discomfort likely because of extreme heat or cold. They may also be used to estimate the likelihood of superstructure icing.

Ice accretion is a complicated process that depends upon sea conditions, temperature, wind and the size and behavior of the ship. Superstructure icing can affect all ships but is more dangerous for smaller vessels. Icing potential exists when the air temperature falls below the freezing temperature of sea water (usually about  $-2^{\circ}\text{C}$ ) with wind speed equal to or greater than 11 knots. The lower the temperature and higher the wind speed, the greater the icing potential. Ice accretion may become quite severe with temperatures  $\leq -9^{\circ}\text{C}$  and wind  $\geq 34$  knots.

## SEA SURFACE TEMPERATURE

Sea surface temperature is recorded with fairly high frequency in marine observations. The 1% and 99% isopleths give estimates of the extremes that may be encountered at any location. The graphs are simple cumulative percent frequency presentations. The temperature range and scale on the graphs may vary from area to area and month to month.

Sea surface temperature can be used to estimate the approximate time a person in ordinary clothes and life preserver may be expected to survive in the water:

<i>Water Temperature</i>	<i>Exhaustion or Unconsciousness</i>	<i>Expected Time of Survival</i>
$< 0^{\circ}\text{C}$	$< 15$ min	$< 15-45$ min
$0-5^{\circ}\text{C}$	15-30 min	30-90 min
$5-10^{\circ}\text{C}$	30-60 min	1-3 hrs
$10-15^{\circ}\text{C}$	1-2 hrs	1-6 hrs
$15-20^{\circ}\text{C}$	2-7 hrs	2-40 hrs
$20-25^{\circ}\text{C}$	3-12 hrs	3 to indefinite hrs
$> 25^{\circ}\text{C}$	Indefinite	Indefinite

## HUMIDITY

Moisture content of the atmosphere is an element which has been recorded relatively infrequently in marine observations. The 1% and 99% dew-point temperature isopleths give estimates of extremes of this element that may be encountered at any location.

The graph depicts wet bulb and relative humidity information. The cumulative percent frequency of wet-bulb temperatures may be read from the solid line with reference to values on the scale at the top of the graph. Relative humidity may be read from the dashed line with reference to the scale at the bottom of the graph.

## PRECIPITATION

Precipitation charts and graphs are intended to depict the frequency of precipitation at the time of the observation. Based on work done in connection with Volume I (Revised) North Atlantic Ocean, present weather codes 20-27 (precipitation within the past hour) were counted in precipitation frequencies to correct an apparent observational bias. The graphs show precipitation by wind direction. The percent frequency of all observations which reported precipitation is printed in the upper right corner of each graph. The

distribution of precipitation by wind direction (and calm) is given by the bar graph. This graph is based on precipitation frequency and not on wind direction frequency. The reader should refer to the surface wind chart if he is interested in the wind direction and speed distribution.

No isopleths were drawn for the percent frequency of precipitation observations reporting snow because of inadequate data. However, graphs for some of the representative areas do reflect the presence of snow.

## VISIBILITY

The cumulative percent frequency of horizontal visibility is presented by nautical mile class intervals rather than by kilometers. The percentage of horizontal visibility equal to or greater than 25 nautical miles can be obtained by subtracting from 100% the cumulative percent frequency at the point  $< 25$  on each graph. Caution is advised, however, in interpreting these areas since, because of curvature of the earth, it is virtually impossible to see 25 miles horizontally from the bridge of most ships. The supplemental table at the bottom of the graph gives percentage of visibilities  $< 2$  nautical miles which occurred with each wind direction and calm.

## CLOUD COVER

Even with the increased data base, the quality and quantity of low cloud data is quite poor. The total cloud amount element does not suffer from this deficiency to so great an extent. The number of observations available which contain only total cloud amount continues to be higher than those containing both total and low. The use of satellite data also bolsters confidence in the total cloud statistics. Cloud patterns derived from the marine observations and those depicted by satellites show fairly close agreement (U.S. Department of Commerce and United States Air Force, 1971).

The observation count on the graphs is that of observations containing total cloud amount. The low cloud curve on the graph is based on less data than the total cloud curve. This may lead to inconsistencies where low cloud amount appears higher than the total cloud amount. In all cases these were resolved in favor of the total cloud by making the frequency curves coincide.

The cumulative percent frequency of a cloud amount equal to or less than the amount intersected by the curve may be read for total cloud along the solid line or low cloud along the dashed line. The percent frequency of obscurations may be determined by subtracting the cumulative percent frequency corresponding to 8/8 coverage from 100%. The bar

graph portion of the figure shows the percent frequency of low cloud amount equal to or greater than 5/8 and equal to or greater than 7/8 for each wind direction and calm. Total sky obscurations are considered as 8/8 coverage for these purposes.

## CEILING AND VISIBILITY

Simultaneous ceiling-visibility contingencies are presented in isopleth and tabular form. They are designed as an aid to situations where both vertical and horizontal visibility are the major items of concern. Since an "aircraft" type ceiling value is not available, the ceiling height is estimated from the height of low cloud (h) when the amount of low cloud ( $N_h$ ) is greater than 4/8. Total sky obscurations are considered to be ceilings. If they are ground-based, they are considered to have a height equal to zero.

## WIND - VISIBILITY - CLOUDINESS

This series of charts is designed to give the planner an estimate of the probability of occurrence of certain significant operational conditions. The conditions for optimum and poor carrier operations are those recommended by the users of the earlier atlas series. Of the elements used in these statistics, height of low cloud ceiling has the least reliability in the case of transient ship observations.

It should be noted that in both the contingency tables and the isopleths, the poor carrier operation conditions are *and/or* situations. This means if any one of the poor conditions of ceiling, visibility or wind speed exists, the event is counted as *poor*. However, in the case of optimum conditions it is an *and* situation. That is, the ceiling must be  $\geq 5000$  feet and visibility  $\geq 5$  nautical miles and wind 11-21 knots.

## SEA LEVEL PRESSURE AND MEAN WIND

Two sets of wind statistics are presented. The vector mean wind is shown by arrows (direction of flow toward the station dot with the resultant magnitude of the vector plotted at the end of the arrow). The scalar mean speed without regard to direction is shown by isopleth analysis. In areas of high persistence of direction, the magnitude of the mean vector should approximate the scalar mean speed. Pressure graphs and charts are also shown.

## WAVES ( $<1.5$ AND $<2.5$ METERS)

In these analyses, the higher of the sea or swell is selected

graph portion of the figure shows the percent frequency of low cloud amount equal to or greater than 5/8 and equal to or greater than 7/8 for each wind direction and calm. Total sky obscurations are considered as 8/8 coverage for these purposes.

## CEILING AND VISIBILITY

Simultaneous ceiling-visibility contingencies are presented in isopleth and tabular form. They are designed as an aid to situations where both vertical and horizontal visibility are the major items of concern. Since an "aircraft" type ceiling value is not available, the ceiling height is estimated from the height of low cloud (h) when the amount of low cloud ( $N_h$ ) is greater than 4/8. Total sky obscurations are considered to be ceilings. If they are ground-based, they are considered to have a height equal to zero.

## WIND - VISIBILITY - CLOUDINESS

This series of charts is designed to give the planner an estimate of the probability of occurrence of certain significant operational conditions. The conditions for optimum and poor carrier operations are those recommended by the users of the earlier atlas series. Of the elements used in these statistics, height of low cloud ceiling has the least reliability in the case of transient ship observations.

It should be noted that in both the contingency tables and the isopleths, the poor carrier operation conditions are *and/or* situations. This means if any one of the poor conditions of ceiling, visibility or wind speed exists, the event is counted as *poor*. However, in the case of optimum conditions it is an *and* situation. That is, the ceiling must be  $> 5000$  feet and visibility  $> 5$  nautical miles and wind 11-21 knots.

## SEA LEVEL PRESSURE AND MEAN WIND

Two sets of wind statistics are presented. The vector mean wind is shown by arrows (direction of flow toward the station dot with the resultant magnitude of the vector plotted at the end of the arrow). The scalar mean speed without regard to direction is shown by isopleth analysis. In areas of high persistence of direction, the magnitude of the mean vector should approximate the scalar mean speed. Pressure graphs and charts are also shown.

## WAVES ( $<1.5$ AND $<2.5$ METERS)

In these analyses, the higher of the sea or swell is selected

for summarization. If the heights are equal, the wave with the longer period is selected. In order to present as broad a spectrum of heights and periods as practicable, two sets of wave charts are furnished. The graphs accompanying the low wave charts ( $< 1.5$  and  $< 2.5$  meters) show wave height versus wave direction. The bar graph and the percent scale at the top of the chart give the percent frequency of waves from each direction. Indeterminate directions are combined with calms. The percent frequency of wave heights (bottom scale) may be read for each height interval and wave direction from the contingency table. The isopleth analyses of the percent frequency of heights  $< 1.5$  and  $< 2.5$  meters are for generally non-hazardous sea conditions.

## WAVES ( $\geq 3.5$ AND $\geq 6$ METERS)

Wave heights in the  $\geq 3.5$  and  $\geq 6$  meter range represent increasingly hazardous conditions. Accompanying these charts are contingency tables of wave period versus wave height.

## TROPICAL CYCLONES

The tropical cyclone movement roses in this atlas are reprinted from the *Mariners Worldwide Climatic Guide to Tropical Storms at Sea*, NAVAIR 50-1C-61, 1974. The data presented here include all tropical cyclones estimated to have wind speeds greater than about 33 knots. All data are combined for each  $5^\circ$  quadrangle. The period of record is 1854-1969 for the Southern Hemisphere; 1877-1970 for the Northern Hemisphere. The reader is referred to the above mentioned "Guide" for more detailed information.

## DURATION OF DAYLIGHT

The Duration of Daylight Chart for the Northern and Southern Hemispheres defines daylight as the period from sunrise to sunset. The upper scale at the bottom of the chart is for the Northern Hemisphere; the lower scale is for the Southern Hemisphere. As an example, the daylight on July 20 of any year at  $48^\circ\text{N}$  is about 15 hours and 30 minutes for any longitude, approximately the same amount of daylight occurs at  $48^\circ\text{S}$  on January 17 for any longitude. The data source was the U.S. Naval Observatory (1945) and is accurate for the entire 20th Century. Further details may be obtained from *The Daylighter* by the U.S. Navy Weather Research Facility (1960). Additional light (during twilight) may be usable for many purposes. Duration of daylight in high latitudes (poleward of about  $60^\circ$ ) becomes increasingly dependent upon atmospheric conditions and refraction and there may be some departure from the values depicted on the charts.

## PART II - OCEANOGRAPHY

### TIDES

The information presented on the charts (types of tides, typical tide curves and tide ranges) were derived primarily from tide tables and tables of tidal harmonic constants. Tidal information is generally adequate for the Indian Ocean except for the region north of the Gulf of Mannar and the western part of the head of the Bay of Bengal, the Crozet Islands in the southwestern part of the Indian Ocean, and in the Gulfs of Carpentaria and Thailand.

### CURRENTS

The ocean current charts are compiled principally from ship drift reports that were forwarded by the various merchant marines to the Naval Oceanographic Office. From these drift observations the sets and average speeds of the prevailing currents are calculated for each 1° quadrangle. The density of observations is greatest along the major shipping lanes and therefore the reliability of the current charts is best in these areas. For the Indian Ocean as a whole, the data is adequate except in the southern part where the data are extremely sparse, and in the central part of the Bay of Bengal. Other areas without adequate data density are: the North and northwest coast of Australia, in the Banda, Ceram and Molucca Seas and off the northwest coasts of Borneo and Palawan, as well as in the Gulfs of Thailand and Tonkin.

The surface currents are shown for four months which are believed to be most representative of the oceans response to the monsoons. The currents for the months of January and July represent ocean current conditions in response to the Northeast and Southwest monsoon seasons respectively. The April and October charts represent ocean surface conditions during the monsoonal transition months.

Where the effect of the monsoons is strongest, e.g., Arabian Sea, Bay of Bengal, and South China Sea, the figures were derived from monthly surface current data. Other regions of the Indian Ocean are less responsive to the monsoon influences and the currents were therefore constructed from seasonal averages adjusted by what monthly data were available to portray the specific months indicated.

Variations from the directions and speeds of the indicated prevailing currents can be expected, especially in areas where the currents are weak.

Tidal currents are shown where they predominate. These are subject to modifications of speed and direction by winds and other nonperiodic variables.

### ICE

#### Sea Ice

The occurrence of sea ice is limited to a small region in the southwestern part of the Indian Ocean.

#### Glacier Ice

The mean maximum limit of drifting glacier ice is based on extremely sparse data derived from published sources.

# MARCH

## 12 hourly movements of tropical cyclone centers (wind speed estimated $\geq 34$ knots).

**Mean speed:** Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

**Direction frequency:** Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

**Vector mean direction and speed:** Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward  $75^\circ$  at 7 knots.)

Statistics for this rose are based on 277 twelve hour movements.

50 individual storms were observed in the  $5^\circ \times 5^\circ$  area during the period of record.

Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.

### Wind speed and air temperature

Percent frequency of simultaneous occurrence of specified temperature (°C) and wind speed (knots)

-(1% of all observations reported temperature 2-3°C simultaneously with wind speed of 22-33 kts.)

indicates  $< 5\%$  but  $> 0$ .

-Number of observations

Use of this table in determination of Potential Superstructure Icing is explained in the text.

BLACK LINE - Percent frequency of T-H index  $\geq 24^{\circ}\text{C}$  ( $75.2^{\circ}\text{F}$ ) (discomfort may be experienced due to heat)

**BLUE LINE** Minimum (1%) air temperature (°C) (1% of the temperatures were equal to or less than the given value)

RED LINE - Maximum (99%) air temperature (°C) (1% of the temperatures were greater than the given value)

# APRIL

## 12 hourly movements of tropical cyclone centers (wind speed estimated $\geq 34$ knots).

Mean speed: Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

Direction frequency: Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

Vector mean direction and speed: Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward  $75^\circ$  at 7 knots.)

Statistics for this rose are based on 277 twelve hour movements.

50 individual storms were observed in the  $5^\circ \times 5^\circ$  area during the period of record.

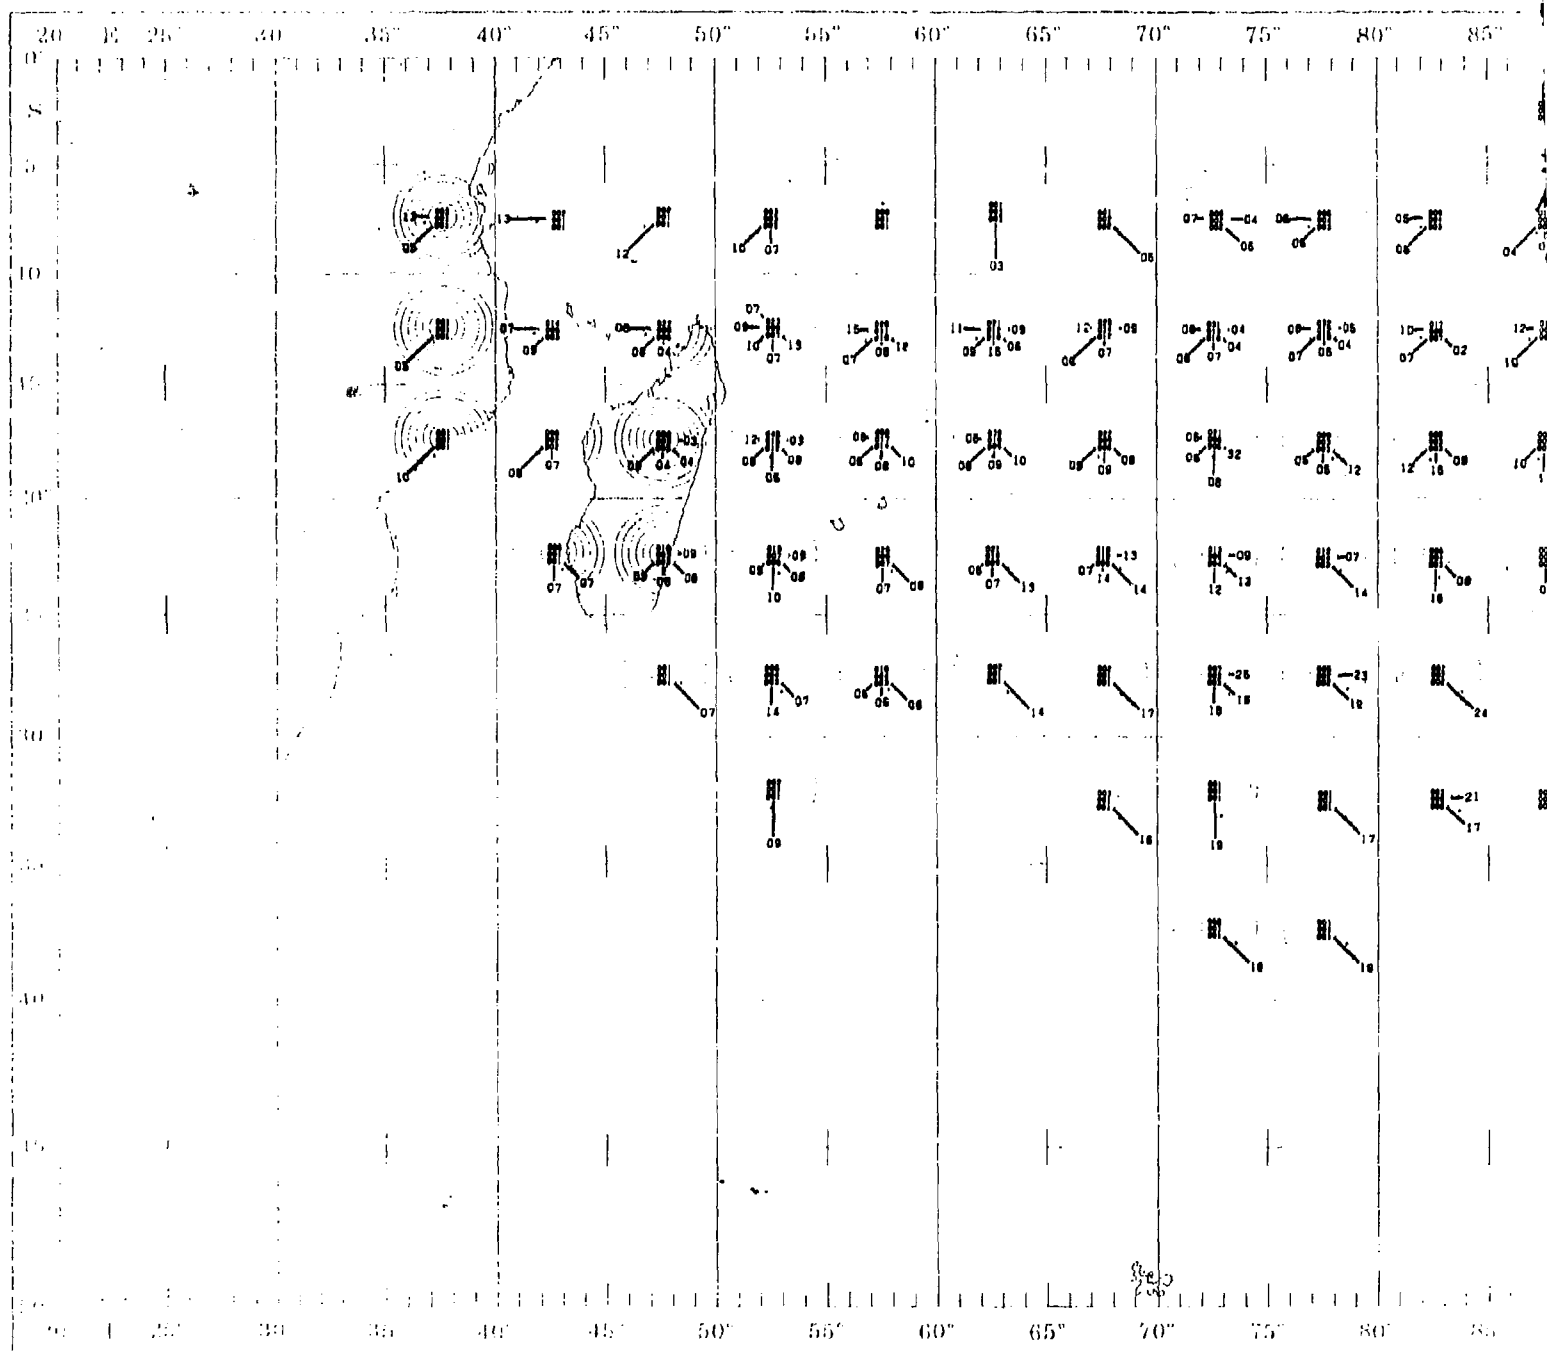

Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.

## 12 hourly movements of tropical cyclone centers (wind speed estimated $\geq 34$ knots).

**Mean speed:** Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

**Direction frequency:** Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

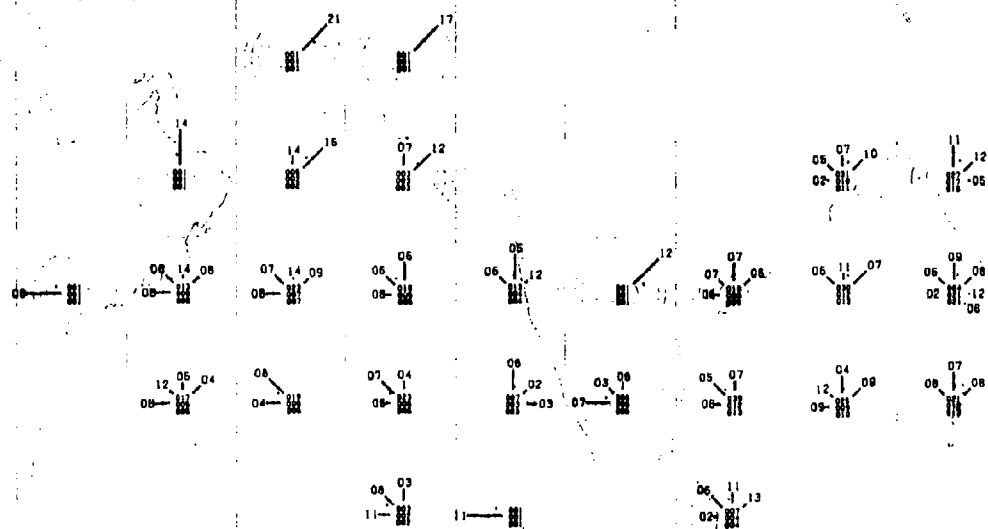

**Vector mean direction and speed:** Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward 75° at 7 knots.)

Statistics for this rose are based on 277 twelve hour movements.

50 individual storms were observed in the 5° X 5° area during the period of record.

Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.

# JUNE

## 12 hourly movements of tropical cyclone centers (wind speed estimated $\geq 34$ knots).

**Mean speed:** Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

**Direction frequency:** Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

**Vector mean direction and speed:** Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward 75° at 7 knots.)

Statistics for this rose are based on 277 twelve hour movements.

50 individual storms were observed in the 5° X 5° area during the period of record.

Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.

~~100~~

Percent frequency of simultaneous occurrence of specified low cloud ceilings (hundreds of feet) and visibilities (nautical miles)

Low cloud ceiling heights are estimated from the height of low clouds ( $h$ ) when low cloud amount ( $N_h$ ) is  $\geq 5/8$

Obscurations are included under ceiling "0 <15"

"N C" (no ceiling) includes bases of clouds  $\geq 8000$  feet as well as occurrences of  $N_h < 5/8$

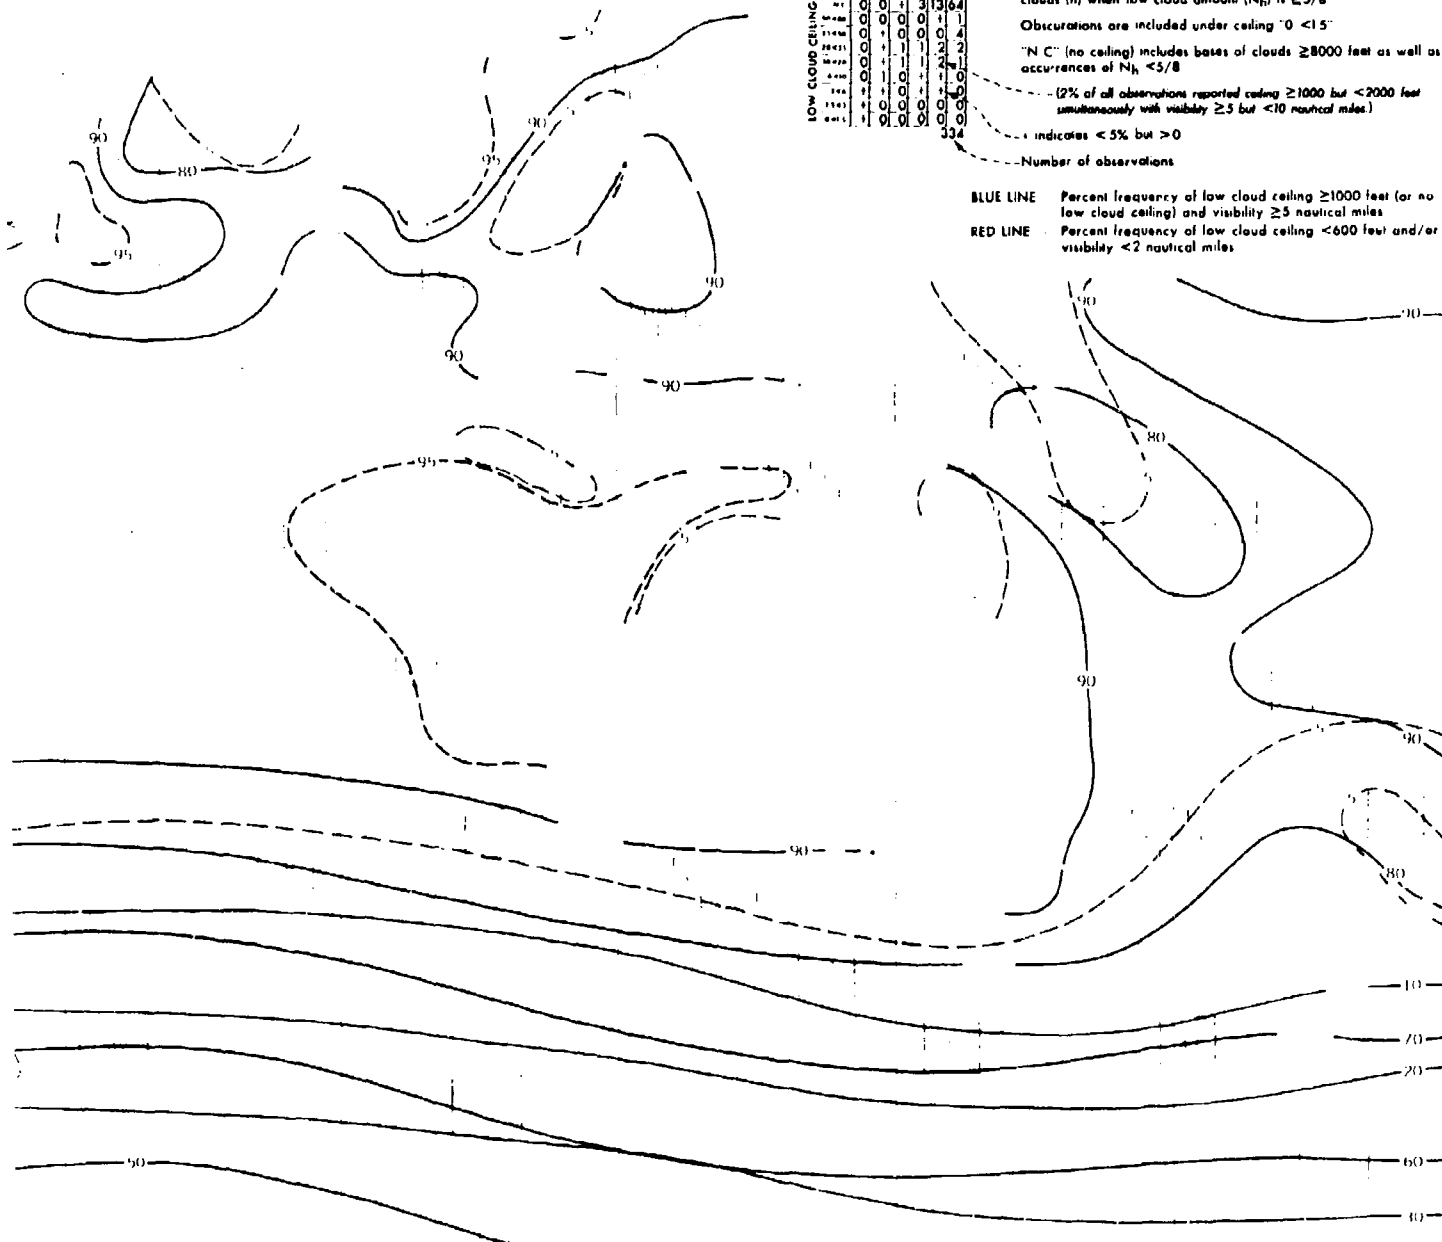

--- (2% of all observations reported coding  $\geq 1000$  but  $< 2000$  feet simultaneously with visibility  $\geq 5$  but  $< 10$  nautical miles.)

... indicates  $< 5\%$  but  $> 0$

-Number of observations

**BLUE LINE** Percent frequency of low cloud ceiling  $\geq 1000$  feet (or no low cloud ceiling) and visibility  $\geq 5$  nautical miles

RED LINE Percent frequency of low cloud ceiling <600 feet and/or visibility <2 nautical miles

[illegible]

# AUGUST

## 12 hourly movements of tropical cyclone centers (wind speed estimated $\geq 34$ knots)

Mean speed: Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

Direction frequency: Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

Vector mean direction and speed: Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward 75° at 7 knots.)

Statistics for this rose are based on 277 twelve hour movements.

50 individual storms were observed in the 5° X 5° area during the period of record.

Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.

# OCTOBER

12 hourly movements of tropical cyclone centers (wind speed estimated  $\geq 34$  knots).

**Mean speed:** Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

**Direction frequency:** Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

**Vector mean direction and speed:** Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward 75° at 7 knots.)

# TROPICAL CYCLONE

01 → 02 → 03 → 04 → 05 → 06 → 07 → 08 → 09 → 10 → 11 → 12 → 13 → 14 → 15 → 16 → 17 → 18

The diagram illustrates a sequence of 18 numbered points (01 to 18) connected by arrows, forming a complex, non-linear path. The points are arranged in a grid-like fashion, with arrows indicating the direction of flow between them. The path starts at point 01, moves to 02, then 03, 04, 05, 06, 07, 08, 09, 10, 11, 12, 13, 14, 15, 16, 17, and finally 18. The arrows show a general downward and then upward trend, with some branching and looping.

OCTOBER

12 hourly movements of tropical cyclone centers (wind speed estimated  $\geq 34$  knots).

Mean speed: Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

**Direction frequency:** Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

— (35% of all tropical cyclones moved toward the NE.)

Vector mean direction and speed: Dot indicates mean vector movement. Each circle equals 10 knots.

—(Mean vector movement of all centers was toward 75° at 7 knots.)

-Statistics for this rose are based on 277 twelve hour movements.

~ 50 individual storms were observed in the 5° X 5° area during the period of record.

~ Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.

# SURFACE AIR TEMPERATURE

— 26

Air Temperature

Number of observations

Cumulative percent frequency of temperatures equal to or less than the temperature intersected by the curve.

(70% of all temperatures were  $\leq 10.3^\circ\text{C}$  or  $\leq 50.5^\circ\text{F}$ .)

S: Standard deviation of temperatures ( $^\circ\text{C}$ )

Mean temperature for each wind direction, calm and for all data combined are represented by dots

(With NW winds, the mean temperature was  $9.4^\circ\text{C}$  or  $48.9^\circ\text{F}$ .)

o Indicates that the mean temperature for a direction or calm was computed from 10-30 observations.

The mean temperature is omitted when less than 10 observations for a direction or calm were available.

BLACK LINE - Mean air temperature ( $^\circ\text{C}$ )

RED LINE - Percent frequency of temperature  $\geq 20^\circ\text{C}$  ( $\geq 68^\circ\text{F}$ )

# NOVEMBER

## 12 hourly movements of tropical cyclone centers (wind speed estimated $\geq 34$ knots).

**Mean speed:** Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

**Direction frequency:** Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

**Vector mean direction and speed:** Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward  $75^\circ$  at 7 knots.)

Statistics for this rose are based on 277 twelve hour movements.

50 individual storms were observed in the  $5^\circ \times 5^\circ$  area during the period of record.

Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.

## Low cloud ceiling - Visibility.

Percent frequency of simultaneous occurrence of specified low cloud ceilings (hundreds of feet) and visibilities (nautical miles).

Low cloud ceiling heights are estimated from the height of low clouds (h) when low cloud amount (N<sub>h</sub>) is  $\geq 5/8$ .

Observations are included under ceiling "0 <1.5".

"N C" (no ceiling) includes bases of clouds  $\geq 8000$  feet as well as occurrences of N<sub>h</sub>  $< 5/8$ .

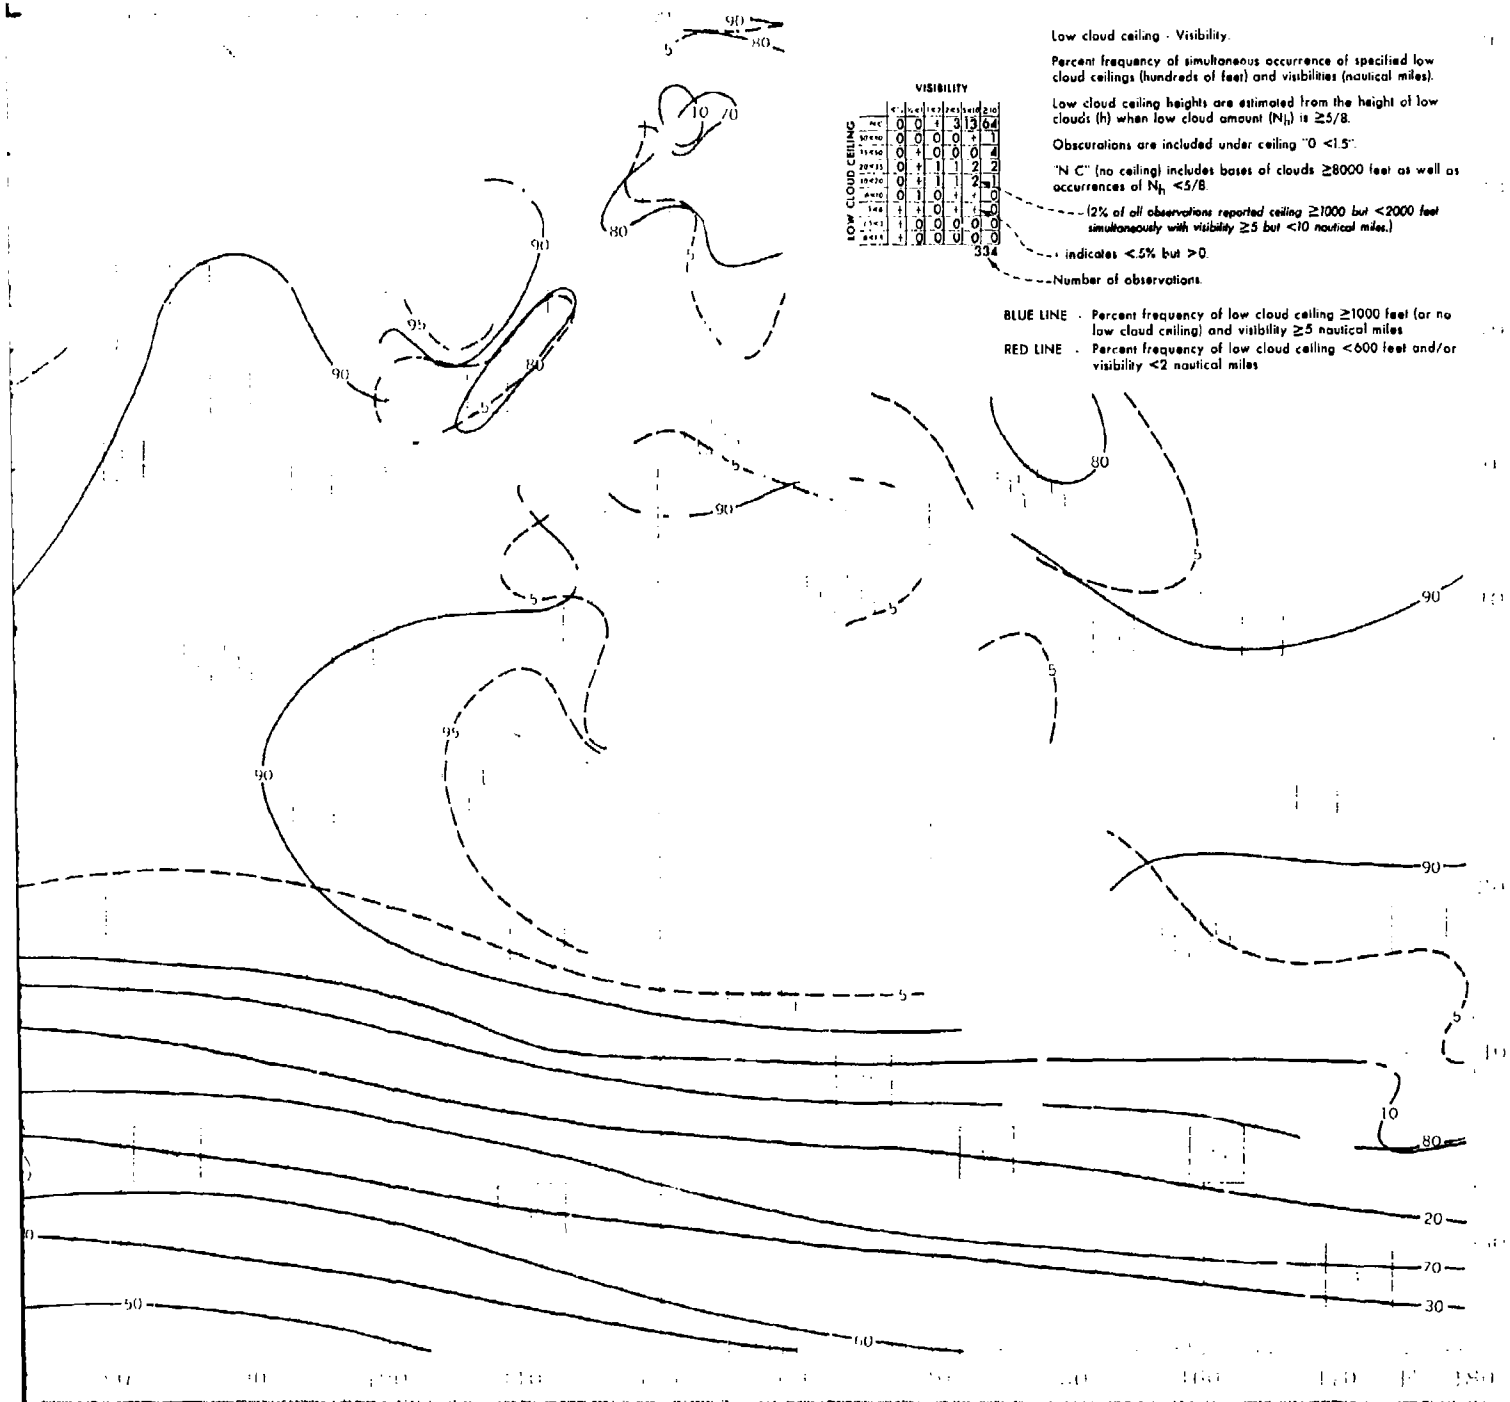

(2% of all observations reported ceiling  $\geq 1000$  but  $< 2000$  feet simultaneously with visibility  $\geq 5$  but  $< 10$  nautical miles.)

indicates  $< 5\%$  but  $> 0$ .

Number of observations.

BLUE LINE - Percent frequency of low cloud ceiling  $\geq 1000$  feet (or no low cloud ceiling) and visibility  $\geq 5$  nautical miles

RED LINE - Percent frequency of low cloud ceiling  $< 600$  feet and/or visibility  $< 2$  nautical miles

# DECEMBER

12 hourly movements of tropical cyclone centers (wind speed estimated  $\geq 34$  knots).

**Mean speed:** Printed figure at the end of each bar represents the mean speed of movement (in knots) toward the indicated direction.

(Centers moving toward the N had a mean speed of 5 knots.)

**Direction frequency:** Bars represent percentage frequency of centers that moved toward each direction. Each circle represents 20%.

(35% of all tropical cyclones moved toward the NE.)

**Vector mean direction and speed:** Dot indicates mean vector movement. Each circle equals 10 knots.

(Mean vector movement of all centers was toward  $75^\circ$  at 7 knots.)

Statistics for this rose are based on 277 twelve hour movements.

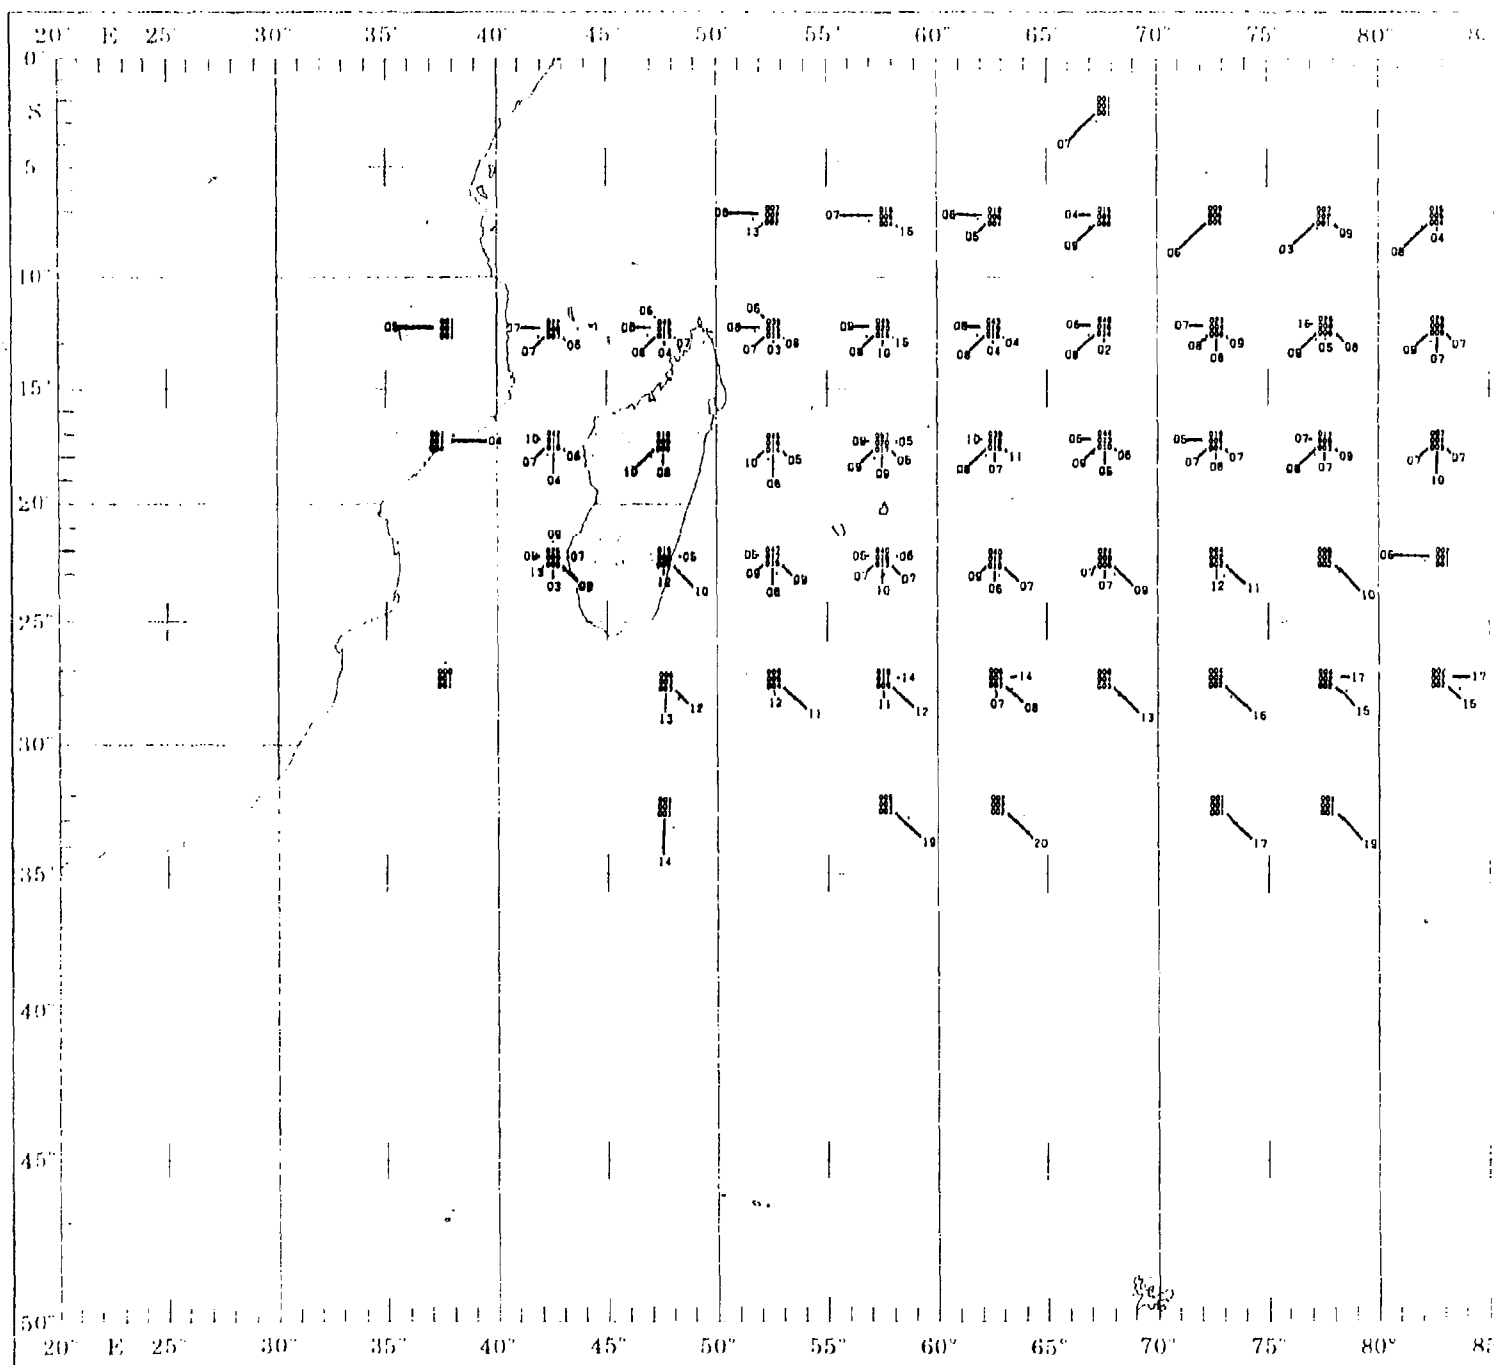

50 individual storms were observed in the  $5^\circ \times 5^\circ$  area during the period of record.

Probability of having at least one tropical cyclone in this area in any given year for this month is 26%.
